Duolingo MOD APK: Learn Languages Free v5.1.5 (Unlocked).SPID#: 10 For their first published paper on the physical basis of cell division, the authors have made a major advance in the field. Dr. John H.W. Tinsley and colleagues have shown that most mitosis (the process by which cells divide) is driven by the forces exerted by microtubules (long, thread-like cell structures that run down the length of the cell). Their findings suggest that the mechanical forces generated by the microtubule network -- together with the direction and timing of the cell division -- influence the characteristics of the daughter cells that result from each cell division. This study complements earlier work by the same group which first described how the microtubule network oscillates. This oscillation may coordinate the events of mitosis and cytokinesis, and has been found in all eukaryotic cell types studied thus far. In this study, the authors measure the forces of the microtubule network in single cells. For this purpose, they integrated an optical trap with a fluorescence microscope, and then imaged the physical forces exerted by the microtubules as a cell undergoes mitosis. They observe that within a set interval of time during mitosis, the microtubule network generates a force
